Search Strategy

PubMed, EMBASE and the Cochrane Central Register of Controlled Trials databases were searched using the terms (“stroke” and “hypertension” or “secondary prevention” or “blood pressure”). Titles and abstract of each article were reviewed for relevance. Bibliographies were reviewed to find additional relevant articles. Articles were excluded if they were: non-English, commentaries, case-studies, narrative, book chapters, editorials, non-systematic review, or conference abstracts. Additional searches for relevant best practice guidelines were completed and included in a separate section of the review. A total of 40 articles and 9 guidelines were included and were separated into separate categories designed to answer specific questions.

Published Guidelines

Guideline	Recommendations
<p>Rabi DM, McBrien KA, Sapir-Pichhadze R, et al.</p> <p>Hypertension Canada's 2020 Comprehensive Guidelines for the Prevention, Diagnosis, Risk Assessment, and Treatment of Hypertension in Adults and Children.</p> <p>Canadian Journal of Cardiology 2020; 36: 596-624.</p> <p>(selected)</p>	<p><i>Hypertension and Stroke XI.</i></p> <p>Treatment of hypertension in association with stroke Recommendations</p> <p>A. BP management in acute ischemic stroke (onset to 72 hours) 1. For guidelines on BP management in acute ischemic stroke, refer to the current Canadian Stroke Best Practices recommendations (www.strokebestpractices.ca/recommendations).</p> <p>B. BP management after acute ischemic stroke 1. Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack (Grade A). 2. After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently < 140/90 mm Hg (Grade C). 3. Treatment with an ACE inhibitor and thiazide/thiazidelike diuretic combination is preferred (Grade A). 4. For patients with stroke, the use of an ACE inhibitor with an ARB is not recommended (Grade B).</p> <p>C. BP management in hemorrhagic stroke (onset to 72 hours) 1. For guidelines on BP management in acute hemorrhagic stroke, refer to the current Canadian Stroke Best Practices recommendations</p>

<p>Williams B, Mancia G, Spiering W, Agabiti Rosei E, Azizi M, Burnier M, Clement DL, Coca A, de Simone G, Dominiczak A, Kahan T.</p> <p>2018 ESC/ESH Guidelines for the management of arterial hypertension.</p> <p>Eur Heart J. 2018;39(33):3021-3104</p> <p>(selected)</p>	<p><i>Therapeutic strategies in hypertensive patients with acute stroke and cerebrovascular disease</i></p> <p>In patients with acute intracerebral haemorrhage:</p> <ul style="list-style-type: none"> • Immediate BP lowering is not recommended for patients with SBP <220 mmHg. Class III; Level A • In patients with SBP >_220 mmHg, careful acute BP lowering with i.v. therapy to <180 mmHg should be considered. Class IIa; Level B <p>In acute ischaemic stroke, routine BP lowering with antihypertensive therapy is not recommended, with the exceptions: Class III; Level A</p> <ul style="list-style-type: none"> • In patients with acute ischaemic stroke who are eligible for i.v. thrombolysis, BP should be carefully lowered and maintained at <180/105 mmHg for at least the first 24 h after thrombolysis. Class IIa; Level B • In patients with markedly elevated BP who do not receive fibrinolysis, drug therapy may be considered, based on clinical judgement, to reduce BP by 15% during the first 24 h after the stroke onset. Class IIb; Level C <p>In hypertensive patients with an acute cerebrovascular event, antihypertensive treatment is recommended:</p> <ul style="list-style-type: none"> • Immediately for TIA. Class I; Level A • After several days in ischaemic stroke. Class I; Level A <p>In all hypertensive patients with ischaemic stroke or TIA, an SBP target range of 120–130 mmHg should be considered. Class IIa; Level B</p> <p>The recommended antihypertensive drug treatment strategy for stroke prevention is a RAS blocker plus a CCB or a thiazide like diuretic. Class I; Level A.</p>

Guideline	Recommendations
<p>Whelton PK, Carey RM, Aronow WS, Casey DE Jr, Collins KJ, Dennison Himmelfarb C, DePalma SM, Gidding S, Jamerson KA, Jones DW, MacLaughlin EJ, Muntner P, Ovbiagele B, Smith SC Jr, Spencer CC, Stafford RS, Taler SJ, Thomas RJ, Williams KA Sr, Williamson JD, Wright JT Jr.</p> <p>2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/ NMA/PCNA guideline for the prevention, detection, evaluation, and management of high blood pressure in adults: executive summary: a report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines.</p> <p><i>Hypertension</i>. 2018;71:1269–1324.</p> <p>(selected)</p>	<p><i>Recommendations for Treatment of Hypertension for Secondary Stroke Prevention</i></p> <ol style="list-style-type: none"> 1. Adults with previously treated hypertension who experience a stroke or transient ischemic attack (TIA) should be restarted on antihypertensive treatment after the first few days of the index event to reduce the risk of recurrent stroke and other vascular events. COE 1; LOE A 2. For adults who experience a stroke or TIA, treatment with a thiazide diuretic, ACE inhibitor, or ARB, or combination treatment consisting of a thiazide diuretic plus ACE inhibitor, is useful. COE 1; LOE A 3. Adults not previously treated for hypertension who experience a stroke or TIA and have an established BP of 140/90 mm Hg or higher should be prescribed antihypertensive treatment a few days after the index event to reduce the risk of recurrent stroke and other vascular events. COE 1; LOE B-R 4. For adults who experience a stroke or TIA, selection of specific drugs should be individualized on the basis of patient comorbidities and agent pharmacological class. COE 1; LOE B-NR 5. For adults who experience a stroke or TIA, a BP goal of less than 130/80 mm Hg may be reasonable. COE IIb LOE B-R 6. For adults with a lacunar stroke, a target SBP goal of less than 130 mm Hg may be reasonable. COE IIb LOE B-R
<p>Nerenberg KA, Zarnke KB, Leung AA, Dasgupta K, Butalia S, McBrien K, Harris KC, Nakhla M, Cloutier L, Gelfer M, Lamarre-Cliche M.</p> <p>Hypertension Canada’s 2018 Guidelines for Diagnosis, Risk Assessment, Prevention, and Treatment of Hypertension in Adults and Children.</p> <p><i>Can J Cardiol</i> 2018 May 1;34(5):506-25.</p>	<p>BP management after acute ischemic stroke</p> <ol style="list-style-type: none"> 1. Strong consideration should be given to the initiation of antihypertensive therapy after the acute phase of a stroke or transient ischemic attack (Grade A). 2. After the acute phase of a stroke, BP-lowering treatment is recommended to a target of consistently < 140/90 mm Hg (Grade C). 3. Treatment with an ACE inhibitor and thiazide/ thiazide-like diuretic combination is preferred (Grade B). 4. For patients with stroke, the combination of an ACE inhibitor and ARB is not recommended (Grade B).
<p>Clinical Guidelines for Stroke Management 2017. Melbourne (Australia): National Stroke Foundation. Section 4 Secondary Prevention</p>	<p>Strong Recommendation</p> <ul style="list-style-type: none"> • All stroke and TIA patients, with a clinic blood pressure of >140/90mmHg should have long term blood pressure lowering therapy initiated or intensified. • Blood pressure lowering therapy should be initiated or intensified before discharge for those with stroke or TIA, or soon after TIA if the patient is not admitted.

Guideline	Recommendations
	<ul style="list-style-type: none"> Any of the following drug classes are acceptable as blood pressure lowering therapy; angiotensin-converting-enzyme inhibitor, angiotensin II receptor antagonists, calcium channel blocker, thiazide diuretics. Beta-blockers should not be used as first-line agents unless the patient has ischaemic heart disease. <p>Weak Recommendation</p> <ul style="list-style-type: none"> In patients with a systolic blood pressure of 120-140mmHg who are not on treatment, initiation of antihypertensive treatment is reasonable, with best evidence for dual (ACEI/diuretic) therapy. The ideal long-term blood pressure target is not well established. A target of <130mmHg systolic may achieve greater benefit than a target of 140mmHg systolic, especially in patients with stroke due to small vessel disease, provided there are no adverse effects from excessive blood pressure lowering.
<p>Leung AA, Daskalopoulou SS, Dasgupta K, McBrien K, Butalia S, Zarnke KB, et al. for Hypertension Canada,</p> <p>Hypertension Canada’s 2017 Guidelines for Diagnosis, Risk Assessment, Prevention, and Treatment of Hypertension in Adults. <i>Canadian Journal of Cardiology</i> 2017 May;33(5):557-576</p> <p>(selected)</p>	<ol style="list-style-type: none"> Antihypertensive therapy should be prescribed for average DBP measurements of ≥100 mmHg (Grade A) or average SBP measurements of ≥160 mmHg (Grade A) in patients without macrovascular target organ damage or other cardiovascular risk factors. Antihypertensive therapy should be strongly considered for average DPB readings ≥90 mmHg (Grade A) or for average SBP readings ≥140 mmHg (Grade B for 140-160 mmHg; Grade A for >160 mmHg; revised guideline) in the presence of macrovascular target organ damage or other independent cardiovascular risk factors.
<p>Intercollegiate Stroke Working Party. Royal College of Physicians. National Clinical guidelines for stroke. 5th Edition 2016, Edinburgh, Scotland</p>	<p>A- People with stroke or TIA should have their blood pressure checked, and treatment should be initiated and/or increased as tolerated to consistently achieve a clinic systolic blood pressure below 130 mmHg, except for people with severe bilateral carotid artery stenosis, for whom a systolic blood pressure target of 140–150 mmHg is appropriate.</p> <p>B- For people with stroke or TIA aged 55 or over, or of African or Caribbean origin at any age, antihypertensive treatment should be initiated with a long-acting dihydropyridine calcium channel blocker or a thiazide-like diuretic. If target blood pressure is not achieved, an angiotensin converting enzyme inhibitor or angiotensin II receptor blocker should be added.</p> <p>C- For people with stroke or TIA not of African or Caribbean origin and younger than 55 years, antihypertensive treatment should be initiated with an angiotensin converting enzyme inhibitor or an angiotensin II receptor blocker.</p> <p>D- Blood pressure-lowering treatment for people with stroke or TIA should be initiated prior to the transfer of care out of hospital or at 2 weeks, whichever is the soonest, or at the first clinic visit for people not admitted.</p> <p>E- Blood pressure-lowering treatment for people with stroke or TIA should be monitored frequently and increased to achieve target blood pressure as quickly as tolerated and safe in primary care. People whose blood pressure remains above target despite treatment should be checked for medication adherence before being referred for a specialist opinion.</p>

Guideline	Recommendations
<p>Kernan WN, Ovbiagele B, Black HR, Bravata DM, Chimowitz MI, Ezekowitz MD, Fang MC, Fisher M, Furie KL, Heck DV, Johnston SC, Kasner SE, Kittner SJ, Mitchell PH, Rich MW, Richardson D, Schwamm LH, Wilson JA.</p> <p>Guidelines for the prevention of stroke in patients with stroke and transient ischemic attack: a guideline for healthcare professionals from the American heart association/American stroke association.</p> <p><i>Stroke</i> 2014;45:2160-2236.</p>	<ul style="list-style-type: none"> Initiation of BP therapy is indicated for previously untreated patients with ischemic stroke or TIA who, after the first several days, have an established BP ≥ 140 mm Hg systolic or ≥ 90 mm Hg diastolic (Class I; Level of Evidence B). Initiation of therapy for patients with BP < 140 mm Hg systolic and < 90 mm Hg diastolic is of uncertain benefit (Class IIb; Level of Evidence C). Clarification of parameters for initiating BP therapy Resumption of BP therapy is indicated for previously treated patients with known hypertension for both prevention of recurrent stroke and prevention of other vascular events in those who have had an ischemic stroke or TIA and are beyond the first several days (Class I; Level of Evidence A). Clarification of parameters for resuming BP therapy Goals for target BP level or reduction from pretreatment baseline are uncertain and should be individualized, but it is reasonable to achieve a systolic pressure < 140 mm Hg and a diastolic pressure < 90 mm Hg (Class IIa; Level of Evidence B). For patients with a recent lacunar stroke, it might be reasonable to target a systolic BP of < 130 mm Hg (Class IIb; Level of Evidence B). Several lifestyle modifications have been associated with BP reductions and are a reasonable part of a comprehensive antihypertensive therapy (Class IIa; Level of Evidence C). These modifications include salt restriction; weight loss; the consumption of a diet rich in fruits, vegetables, and low-fat dairy products; regular aerobic physical activity; and limited alcohol consumption. The optimal drug regimen to achieve the recommended level of reductions is uncertain because direct comparisons between regimens are limited. The available data indicate that diuretics or the combination of diuretics and an angiotensin-converting enzyme inhibitor is useful (Class I; Level of Evidence A). The choice of specific drugs and targets should be individualized on the basis of pharmacological properties, mechanism of action, and consideration of specific patient characteristics for which specific agents are probably indicated (eg, extracranial cerebrovascular occlusive disease, renal impairment, cardiac disease, and DM) (Class IIa; Level of Evidence B).
<p>Meschia JF, Bushnell C, Boden-Albala B, Braun LT, Bravata DM, Chaturvedi S, et al; on behalf of the American Heart Association Stroke Council, Council on Cardiovascular and Stroke Nursing, Council on Clinical Cardiology, Council on Functional Genomics and Translational Biology, and Council on Hypertension.</p> <p>Guidelines for the primary prevention of stroke: a statement for healthcare</p>	<ol style="list-style-type: none"> Regular BP screening and appropriate treatment of patients with hypertension, including lifestyle modification and pharmacological therapy, are recommended (Class I; Level of Evidence A). Annual screening for high BP and health-promoting lifestyle modification are recommended for patients with prehypertension (SBP of 120 to 139 mmHg or DBP of 80 to 89 mmHg) (Class I; Level of Evidence A). Patients who have hypertension should be treated with antihypertensive drugs to a target BP of $< 140/90$ mmHg (Class I; Level of Evidence A). Successful reduction of BP is more important in reducing stroke risk than the choice of a specific agent, and treatment should be individualized on the basis of other patient characteristics and medication tolerance (Class I; Level of Evidence A). Self-measured BP monitoring is recommended to improve BP control. (Class I; Level of Evidence A).

Guideline	Recommendations

<p>James PA, Oparil S, Carter BL, et al.</p> <p>2014 evidence-based guideline for the management of high blood pressure in adults: report from the panel members appointed to the Eighth Joint National Committee (JNC 8).</p> <p><i>JAMA</i> 2014; 311: 507-20 (selected)</p>	<p>Recommendation 1 In the general population aged 60 years, initiate pharmacologic treatment to lower blood pressure (BP) at systolic blood pressure (SBP) ≥ 150 mm Hg or diastolic blood pressure (DBP) ≥ 90 mm Hg and treat to a goal SBP < 150 mm Hg and goal DBP < 90 mm Hg. (Strong Recommendation – Grade A)</p> <p>Recommendation 2 In the general population < 60 years, initiate pharmacologic treatment to lower BP at DBP ≥ 90 mm Hg and treat to a goal DBP < 90 mmHg. (For ages 30-59 years, Strong Recommendation – Grade A; For ages 18-29 years, Expert Opinion – Grade E)</p> <p>Recommendation 3 In the general population < 60 years, initiate pharmacologic treatment to lower BP at SBP ≥ 140 mm Hg and treat to a goal SBP < 140 mm Hg. (Expert Opinion – Grade E)</p> <p>Recommendation 4 In the population aged ≥ 18 years with chronic kidney disease (CKD), initiate pharmacologic treatment to lower BP at SBP ≥ 140 mmHg or DBP ≥ 90 mmHg and treat to goal SBP < 140 mm Hg and goal DBP < 90 mmHg. (Expert Opinion – Grade E)</p> <p>Recommendation 5 In the population aged ≥ 18 years with diabetes, initiate pharmacologic treatment to lower BP at SBP ≥ 140 mmHg or DBP ≥ 90 mm Hg and treat to a goal SBP < 140 mm Hg and goal DBP < 90 mm Hg. (Expert Opinion – Grade E)</p>

Evidence Tables

Association between Hypertension and Stroke Risk

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
Yano et al. 2018 USA Prospective study	NA	4,851 participants included in the CARDIA study, aged 18 to 30 years who had not experienced any CVD events before age 40 years, who were recruited from 4 US field centers. The mean age when follow-up began was 35.7 years, 45% were men.	Blood pressures were recorded at baseline and at years 2, 5, 7, 10, 15, 20, 25 and 30. Using the highest BP measured from the first examination to the examination closest to, but not after, age 40 years, each participant was categorized as having normal BP at all examinations, elevated BP (SBP 120-129 mm Hg; DBP >80 mm Hg at 1 or more examinations); stage 1 HTN (SBP 130-139 mm Hg; or DBP 80-89 mm Hg at 1 or more examinations) or stage 2 HTN (≥ 140 mm Hg, DBP ≥ 90 mm Hg, or taking antihypertensive medication at 1 or more examinations). The association between future CVD events and HTN was examined.	CVD events: fatal and nonfatal coronary heart disease (CHD), heart failure, stroke, TIA, or intervention for peripheral artery disease (PAD).	<p>2,574 persons had normal BP, 455 had elevated BP, 1,194 had stage 1 HTN and 638 had stage 2 HTN.</p> <p>During a median follow-up of 18.8 years, there were 228 CVD events (CHD, 109; stroke, 63; heart failure, 48; peripheral artery disease, 8 and 319 all-cause deaths.</p> <p>CVD event incidence rates for normal BP, elevated BP, stage 1 HTN and stage 2 HTN were 1.37 (95% CI, 1.07-1.75), 2.74 (95% CI, 1.78-4.20), 3.15 (95% CI, 2.47-4.02), and 8.04 (95% CI, 6.45-10.03) per 1000 person-years, respectively.</p> <p>In the fully adjusted model (including age when follow-up time started, race, sex, educational level, study site, BMI, smoking status, physical activity, total cholesterol, high-density lipoprotein cholesterol, and fasting glucose), the risk of any CVD event was significantly higher among those with elevated, stage 1 and stage 2 HTN, compared with normal BP (HR=1.67, 95% CI 1.01-2.77, HR=1.75, 95% CI 1.22-2.53 and HR= 3.49, 95% CI 2.42-5.05, respectively).</p> <p>The risk of all-cause mortality was significantly higher among those with stage 2 HTN compared with normal BP (adj HR= 2.19, 95% CI 1.61-2.99)</p>
O'Donnell et al. 2016 Canada (International)	NA	Participants were recruited from 32 countries from 2007-2015. Cases were 13,447	All key vascular risk factors (hypertension, DM, smoking, waist-to-hip ratio, diet, physical activity, alcohol intake, psychosocial factors,	The odds of all stroke, ischemic stroke and intracerebral hemorrhagic stroke (ICH) and population attributable risk (PAR)	<p>Self-reported hypertension was associated with an increased risk of stroke.</p> <p>All stroke: OR=2.56, 99% CI 2.33-2.80; PAR 34.4%, 99% CI 32.0-36.9%</p> <p>Ischemic stroke: OR=2.34, 99% CI 2.10-2.60; PAR 32.0%, 99% CI 29.1-35.1%</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
INTERSTROKE Phase 2 Case-control study		<p>persons admitted to hospital within 5 days of first acute stroke and 72 hours of admission to hospital (77% ischemic stroke, 23% ICH). Mean age was 62.2 years. 40.4% of cases were women.</p> <p>13,472 controls were matched for age and sex and were recruited from the community or hospitals (in-patient or outpatient, unrelated to treatment for stroke or TIA)</p>	<p>cardiac causes and ApoB:ApoA1) were collected using questionnaires, physical examinations and blood and urine samples.</p> <p>Hypertension was defined as self-reported or blood pressure $\geq 140/90$ mm Hg</p>		<p>Hemorrhagic stroke: OR=3.71, 99% CI 3.09-4.31; PAR 42.8%, 99% CI 38.9-46.8%</p> <p>Self-reported hypertension or blood pressure $>140/90$ mm Hg was associated with an increased risk of stroke. Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
<p>Rapsomaniki et al. 2014</p> <p>UK</p> <p>Observational study</p>	NA	1,258,006 patients, from the CALIBER database, aged ≥30 years, selected from 225 primary care practices (1997-2010) with no previous history of CVD.	<p>Relationships between hypertension and 12 cardiovascular diseases were explored.</p> <p>Hypertension was defined as ≥140/90 mm Hg. Isolated systolic HTN was defined as ≥140 mm Hg with DBP<90 mm Hg and isolated diastolic HTN as SBP<140 mm Hg and DPB≥90 mm Hg</p>	12 CVD (stable angina, unstable angina, MI, CHD mortality, heart failure, cardiac arrest/sudden cardiac death, TIA, ischemic stroke, SAH, ICH, PAD, AAA and total CVD).	<p>There were 83,098 first cardiovascular events during a median follow-up of 5.2 years.</p> <p>HTN was recorded in 545,816 patients.</p> <p>For each increase of 20/10 mm Hg, the risks were significantly increased for: TIA: HR (SBP)=1.15, 95% CI 1.11-1.19, HR (DBP)=1.15, 95% CI 1.10-1.19 Ischemic stroke: HR (SBP)=1.35, 95% CI 1.28-1.42, HR (DBP)=1.30, 95% CI 1.23-1.38 SAH: HR (SBP)=1.43, 95% CI 1.25-1.63, HR (DBP)=1.42, 95% CI 1.25-1.60 ICH: HR (SBP)=1.44, 95% CI 1.32-1.58, HR (DBP)=1.50, 95% CI 1.37-1.64</p> <p>For each 20/10 mm Hg, the risks of TIA, ischemic stroke and ICH increased across age cohorts (30-59 yrs, 60-79 yrs and ≥80 yrs), with the highest risks noted in the youngest patients.</p> <p>Compared with persons with SBP <115 mm Hg, the pattern of risk of TIA, ischemic stroke, SAH and ICH increased with increasing BP among patients aged 30-59 yrs. The effects were not as pronounced for patients aged 60-79 yrs and there were no significant increased risks for patients ≥80 yrs.</p> <p>The patterns were similar for DBP <75 mm Hg, across all age groups.</p> <p>The lifetime risk of ischemic stroke (from index age of 30 years) in persons with HTN was 7.6% (95% CI 7.3%-7.8%) compared with 6.5% (95% CI 6.2%-6.9%) for persons without HTN.</p>
<p>Bestehorn et al. 2008</p> <p>Germany</p>	NA	47,394 patients under the care of 2,482 general physicians, diagnosed with hypertension	Physicians documented: age, sex and measured current BP, the presence/absence of risk factors including pre-treated hypertension,	<p>Primary outcome: Risk of first stroke within 10 years using the Framingham Stroke Risk (low, medium and high risks are defined as <10%, 10-20%, and >20%).</p>	The most prevalent stroke risk factors were a positive family history of cardiovascular disease (46.1%), diabetes mellitus (36.1%), coronary artery disease (34.4%), and left ventricular hypertrophy (33.3%).

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
Observational study			diabetes mellitus, smoking, atrial fibrillation, left ventricular hypertrophy, coronary artery disease, positive family history and use of current antihypertensive medication.		The mean SBP/DBP was 147/86 mmHg, even though 73.5% of the total cohort was receiving combination therapy for HTN. The mean 10-year risk of stroke was 26% in the total cohort (0–19% in 50.6% of patients, 20–49% in 32.7%, and ≥50% in 16.7%)
Du et al. 2000 UK/USA Case-control study	NA	Patients with first-ever stroke were identified from a community-based stroke register. Cases were <80 years, and registered with a participating practitioner (n=267). Two controls/case from the same practice register were included, matched for age and sex (n=534).	Risk factors were identified through chart review and included HTN (SBP>160 mmHg and/or a DBP> 95 mmHg) on at least two occasions within any three-month period or use of HTN medication. Additional risk factors included history of angina, TIA, MI, atrial fibrillation, diabetes, renal failure, obesity, smoking, family history of stroke and ETOH intake.	Primary outcome: Risk of stroke in subjects with ≥1 multiple risk factors	157 (58.8%) of the cases and 212 (39.7%) of the controls were defined as hypertensive. The risk of stroke was higher among subjects who were hypertensive (adjusted OR=2.45, 95% CI 1.62 to 3.71, p< 0.001). The risk of stroke remained elevated in patients whose HTN was moderately well-controlled (adjusted OR=3.10, 95% CI 1.94 to 4.96) and was no longer significantly elevated among patients who were well-controlled (adjusted OR=1.49, 95% CI 0.8 to 2.49). In hypertensive subjects who were current smokers, the risk of stroke was increased (adjusted OR=6.1, 95% CI 2.7 to 13.7) compared with non-smokers without hypertension. In hypertensive subjects with diabetes, the risk of stroke was increased (adjusted OR=4.22, 95% CI 2.13 to 8.37). In subjects with hypertension + 1, 2 and 3 other risk factor the risk of stroke was increased significantly (adjusted ORs=4.51, 95% CI 2.60 to 7.83; 4.96, 95% CI 2.68 to 9.17 and 9.58, 95% CI 4.74 to 19.34, respectively).

Pharmacological Treatment of Hypertension for Primary and Secondary Prevention of Stroke

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
<i>Systematic reviews & meta-analyses</i>					
<p>Zonneveld et al. 2018</p> <p>The Netherlands</p> <p>Cochrane review</p>	<p>5 trials were considered to be of high methodological quality</p>	<p>11 RCTs, representing data from 38,742 adult participants who had experienced an ischemic or intracerebral hemorrhagic stroke (excluding SAH)</p>	<p>Trials evaluated blood pressure-lowering drugs (BPLDs) started at least 48 hours after stroke or TIA. 8 trials compared BPLDs vs. placebo or no treatment (35,110 participants), and 3 compared intensive vs. standard blood-pressure lowering regimens (n=3,632).</p>	<p>Primary outcome: Recurrent stroke</p> <p>Secondary outcomes: Major vascular event (i.e., composite of cardiovascular death, nonfatal stroke, and nonfatal myocardial infarction),</p>	<p>Median duration of follow-up duration was reported in 6 studies, and ranged from 12 to 47 months.</p> <p>The risk of recurrent stroke was reduced significantly with BPLDs, when compared with placebo or no treatment (RR=0.81, 95% CI 0.70-0.93). Based on results from 8 trials of moderate-quality. The effect was most pronounced (i.e. significant) for persons with baseline SBP>140 mm Hg. ACE inhibitors and diuretics were the most effect antihypertensive agents. The risk of a major vascular event was not reduced significantly with BPLDs (RR=0.9, 95% CI (0.78-1.04). Based on the results from 4 high-quality trials.</p> <p>Intensive blood pressure-lowering vs. standard did not reduce the risks of recurrent stroke, time to recurrent stroke, risk of major vascular event, myocardial infarction, or all-cause mortality.</p>
<p>Bangalore et al. 2017</p> <p>USA</p>	<p>One trial was classified as low risk of bias, fulfilling all criteria (sequence generation of allocation; CA and blinding). All other trials had ≥1 component rated as having an unclear risk of bias</p>	<p>17 RCTs published between 1994 and 2015 including data from 55,163 participants, with/without previous stroke, with/without diabetes, with/without kidney disease, and/or with/without hypertension. Trials included those aged ≥40 years, and those aged ≥70 years.</p>	<p>Trials comparing different goal SBP targets (<150, <140, <130 and <120 mm Hg) against a reference standard of <160 mm Hg.</p>	<p>Primary outcomes: Stroke, MI, death, cardiovascular death, heart failure</p> <p>Safety outcomes: Serious adverse events</p>	<p>Mean duration of follow-up was 3.7 years (204,103 patient-years).</p> <p>Stroke: The risk of stroke was decreased in a comparison of target SBP <120 vs. <160 mm Hg (RR=0.54, 95% CI 0.29-1.00). There were no significant reductions in risk for any of the other pairings (<150 vs. <160 mm Hg; <140 vs. <160 mm Hg; <130 vs. <160 mm Hg).</p> <p>Compared with a target SBP of <120 mm Hg, the risk of stroke was significantly increased with SBP <140 mm Hg (RR=1.72, 95% CI 1.42-2.58), <150 mm Hg (RR=1.97, 95% CI 1.26-3.08) and <160 mm Hg (RR=3.27, 95% CI 1.78-6.00).</p> <p>SBP targets of <120 and <130 mmHg were deemed best for stroke prevention.</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
					<p>MI: The risk of MI was decreased in a comparison of target SBP <120 vs. <160 mm Hg (RR=0.68, 95% CI 0.47-1.00). There were no significant reductions in risk for any of the other pairings (<150 vs. <160 mm Hg; <140 vs. <160 mm Hg; <130 vs. <160 mm Hg).</p> <p>All other primary outcomes: There were no significant reductions in the risks of death, cardiovascular death, or heart failure when comparing any of the BP targets.</p> <p>Safety: The risks of serious adverse events were significantly increased with SBP targets of <120 vs <150 mm Hg (RR= 1.83, 95% CI, 1.05-3.20) and <120 vs <140 mm Hg (RR= 2.12; 95% CI, 1.46-3.08).</p> <p>BP targets of <140 mm Hg and <150 mm Hg were the safest targets for the outcome of serious adverse effects.</p> <p>An SBP target of <130 mm Hg had optimal balance between efficacy and safety.</p>
<p>Katsanos et al. 2017</p> <p>Greece</p>	<p>The risks of attrition and detection bias were considered unclear in many trials. The risks of performance and detection bias were considered high in 2 studies. The risks of reporting bias and selection</p>	<p>14 RCTs including 42,736 participants with a history of stroke. Mean age at baseline ranged from 59 to 71.8 years.</p>	<p>Trials compared antihypertensive agents vs. placebo (n=11), more intensive vs. less intensive BP control (n=2) and comparison of antihypertensive agents (n=1).</p>	<p>Primary outcomes: Recurrent stroke, ischemic stroke, ICH, disabling or fatal stroke, MI, all-cause mortality, cardiovascular mortality</p>	<p>The mean duration of follow-up ranged from 12-60 months.</p> <p>The risks of recurrent stroke, disabling or fatal stroke and cardiovascular death were all significantly reduced with antihypertensive treatment compared with placebo (RR=0.73, 95% CI 0.62–0.87, p <0.001 [results from 11 studies included], RR=0.71, 95% CI 0.59–0.85, <0.001 [results of 7 studies included], and RR=0.85, 95% CI 0.75–0.96, p=0.01 [results of 8 studies included], respectively. The risks of ischemic stroke, hemorrhagic stroke, MI or death from any cause were not reduced significantly.</p> <p>In subgroup analysis, lower SBP was associated with lower frequency of recurrent stroke (<130 vs.</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
	bias were considered low.				<p>130-140 vs. ≥ 140 mm Hg; 8.3% vs. 9.2% vs. 11.7%, $p=0.048$) and cardiovascular death (0.8% vs. 3.3% vs. 5.5%, $p=0.49$).</p> <p>In meta-regression analysis, increasingly lower SBP was linearly associated with significant reductions in recurrent stroke, MI, death from any cause and cardiovascular death. Increasingly lower DBP was linearly associated with significant reductions in the risk of recurrent stroke and cardiovascular death.</p>
<p>Ettehad et al. 2016 UK</p>	Ten studies were judged to be of unclear risk of bias and 113 were deemed to be at low risk of bias.	123 studies with 613,815 participants with a minimum of 1,000 patient-years of follow-up	Trials compared blood pressure lowering drug vs. placebo ($n=71$); different blood pressure lowering drugs ($n=31$); more intensive vs. less intensive treatment ($n=9$), active treatment vs. placebo + comparison of active drugs ($n=7$) and more intensive vs. less intensive treatment + comparison of active drugs ($n=5$).	<p>Primary outcomes: Major cardiovascular events, coronary heart disease, stroke, heart failure, renal failure, all-cause mortality</p>	<p>Every 10 mm Hg reduction in SBP significantly reduced the risk of major cardiovascular disease events (RR= 0.80, 95% CI 0.77–0.83), coronary heart disease (RR=0.83, 95% CI 0.78–0.88), stroke (RR=0.73, 95% CI 0.68–0.77), heart failure (RR=0.72, 95% CI 0.67–0.78) and all-cause mortality (RR=0.87, 95%CI 0.84–0.91).</p> <p>The reduction in the risk of major cardiovascular events was proportional to the magnitude of the blood pressure reduction achieved.</p> <p>The risk of stroke was reduced with antihypertensive treatment across different strata of baseline BP (mm Hg), (p for interaction=0.38) <130: RR=0.65, 95% CI 0.27-1.57 $130-139$: RR=0.73, 95% CI 0.62-0.85 $140-149$: RR=0.78, 95% CI 0.70-0.87 $150-159$: RR=0.65, 95% CI 0.54-0.78 ≥ 160: RR=0.70, 95% CI 0.64-0.78</p> <p>The risk of stroke was reduced significantly per each 10 mm Hg decrease in SBP with antihypertensive treatment in persons with and without existing cardiovascular disease (RR=0.74, 95% CI 0.67-0.81 and RR=0.75, 95% CI 0.63-0.89, respectively).</p> <p>The most effective antihypertensive agents for the reduction in stroke risk were angiotensin receptor</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
Xie et al. 2016 Australia	7 trials had Jadad scores <3 and 7 had Jadad scores ≥3	19 RCTs including 44,989 participants, with hypertension, at high risk of cardiovascular or renal disease, or both. 5 trials only included persons with diabetes and 6, with chronic kidney disease. One trial included children. The mean baseline SBP ranged from 123-172 mm Hg and mean DBP ranged from 76-105 mm Hg. Overall, mean BP was 159/92 mm Hg.	Trials compared more intensive vs less intensive blood pressure-lowering treatment, with at least 6 months' follow-up. The BP targets varied among trials.	Primary outcomes: Major cardiovascular events, (MI, stroke, heart failure, or cardiovascular death), separately and combined; nonvascular and all-cause mortality; end-stage kidney disease; and adverse events.	blockers and calcium channel blockers. Beta-blockers were inferior to other classes of antihypertensives. Mean duration of follow-up was 3.8 years. The mean follow-up BP levels were 133/76 mm Hg in the more intensive treatment group and 140/81 mm Hg in the less intensive group. Across all trials, the weighted mean follow-up difference in BP groups was 6.8/3.5 mm Hg. Intensive BP treatment significantly reduced the risk of major CV events (HR=0.86, 95% CI 0.78–0.96, p=0.0050). Based on the results from 14 trials. Intensive BP treatment significantly reduced the risk of stroke (HR=0.78, 95% CI 0.67–0.90, p=0.001). Based on the results from 14 trials. Intensive BP treatment did not significantly reduce the risks of heart failure, end-stage kidney disease, cardiovascular or non-cardiovascular death, or all-cause mortality. There were no differences in major vascular events between groups, based on subgroup analysis defined according to a broad range of baseline characteristics. Absolute benefits were proportional to absolute risk. The risk of severe hypotension was significantly higher in the more intensive group (0.3% vs. 0.1%, RR=2.68, 95% CI 1.21–5.89, p=0.015). The risks of dizziness or adverse events leading to discontinuation of treatment) were not significantly increased in the more intensive group.
Lee et al. 2012 International	NA	11 RCTs representing data from 42,572 participants (794 with previous stroke) who	Comparisons of treatment of tight BP control (SBP <130 mmHg) vs. usual control	Primary outcome: Stroke risk and achieved level of different SBP (intensive vs. usual).	Follow-up duration ranged from 2.6 to 5.3 years. The final mean SBPs, were 126.5mmHg in the intensive treatment arms and 132.6mmHg in the

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
		were at high risk for CVD.	(SBP 130 to 139 mmHg) on subsequent stroke risk. Treatment contrasts included i) active treatment with nisoldipine or enalapril, candesartan, ramipril, perindopril, verapamil- or atenolol-based therapy, trandolapril, fosinopril or amlodipine, vs. placebo or ii) non-specific antihypertensive drug vs. standard treatment	Secondary outcomes: Major vascular event (i.e., composite of cardiovascular death, nonfatal stroke, and nonfatal myocardial infarction), major coronary events, total death, vascular death	conventional arms. The (mean SBP reduction was 6.1mmHg). Tight SBP target was associated with a lower future stroke risk (RR= 0.80; 95% CI, 0.70 to 0.92, p < 0.01), a lower risk of major vascular events (RR= 0.91, 95% CI 0.86 to 0.96; p < 0.001), a lower risk of major coronary events (RR= 0.91, 95% CI 0.85 to 0.98, p< 0.01, but was not associated with a significantly lower risk of total death (RR= 0.95, 95% CI 0.89 to 1.01, p = 0.08). The risk of hypotension or any adverse event was higher in patients in active treatment groups (RR=3.43, 95% CI 2.46 to 4.79, p<0.001 and RR=1.18, 95% CI 1.11 to 1.25, p <0.001, respectively). In subgroup analyses, patients with diabetes, those without a history of CVD, and younger than 65 years, experienced the greatest stroke risk reduction.
Musini 2009 Canada Cochrane review	NA	15 RCTs (n=24,055 subjects ≥ 60 years) with moderate to severe hypertension (SBP≥ 140 mmHg and/or a DBP≥ 90 mmHg)	Comparisons of anti-hypertensive drug therapies including: ACE inhibitors, ARBs, β-blockers, combined α and β-blockers, calcium-channel blockers, diuretics, α-adrenergic blockers, central sympatholytics, direct vasodilators or peripheral adrenergic antagonists vs. placebo or no treatment. Minimum duration of therapy was 1 year. 12/15 trials instituted a stepped care approach to	Primary outcome: Deaths from all causes Secondary outcomes: Fatal MI or rapid cardiac death, fatal strokes, fatal/non-fatal MI, fatal/non-fatal stroke	Follow-up ranged from 1-6 years. Losses to follow-up ranged from <5% to 25% (n=12) or were not reported. Total mortality was lower in patients in the treatment group (1,215 vs. 1,299). RR= 0.90, 95% CI 0.84 to 0.97, p=0.006. Results from 12 trials included. Cardiovascular mortality was lower in patients in the treatment group (493 vs. 613). RR=0.77, 95% CI 0.68 to 0.86, p<0.0001. Results from 10 trials included. Cerebrovascular mortality was lower in patients in the treatment group (136 vs. 194). RR= 0.66, 95% CI 0.53 to 0.82, p=0.0002. Results from 10 trials included.

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
			treatment. In over 70% of trials a thiazide diuretic was the first line drug in the treatment group.		<p>Deaths due to coronary heart disease (CHD) were lower in patients in the treatment groups (296 vs. 346). RR=0.77, 95% CI 0.65 to 0.90, p<0.0001. Results from 9 trials included.</p> <p>There were fewer cases of cardiovascular mortality and morbidity among patients in the treatment groups (1,276 vs. 1,709). RR=0.72, 95% CI 0.68 to 0.77, p<0.0001. Results from 13 trials included.</p> <p>Withdrawals due to adverse events were greater among patients in the treatment group (372 vs. 215). RR= 1.71, 95% CI 1.45 to 2.00, p<0.0001. Results from 3 trials included.</p>
Law et al. 2009 UK Systematic review & meta-analysis	NA	147 RCTs (n=464,000) that included participants with no history of CVD, but a history of HTN (n=27), a history of coronary heart disease, without selection based on blood pressure (CHD)(n=74) and a history of stroke in which participants were treated for HTN according to targets (n=13). The mean age at study entry ranged from 57-64 years.	108 trials compared blood pressure lowering medications vs. placebo (n=92) or usual care (n=16) and 46 trials compared different types of blood pressure medications.	CHD events and stroke	<p>The mean duration of study follow-up ranged from 1.7-4.5 years.</p> <p>There were 22,115 incident stroke events.</p> <p>A blood pressure treatment-associated reduction of 10 mm Hg systolic and 5 mm Hg diastolic was associated with a reduced risk of stroke (RR=0.59, 95% CI 0.52-0.67)</p> <p>The risk of stroke was significantly reduced in trials that included persons with no prior history of stroke, a history of CHD, and a history of stroke.</p> <p>The risk of stroke associated with individual types of medications was significantly reduced: Thiazides: RR=0.62, 95% CI 0.53-0.72 β-blockers: RR=0.83, 95% CI 0.70-0.99 ACE inhibitors: RR=0.78, 95% CI 0.66-0.92 ARBs: no studies Calcium channel blockers: RR=0.66, 95% CI 0.58-0.75 Overall: RR=0.73, 95% CI 0.66-0.80</p> <p>The risk of stroke in drug comparison trials was:</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
					<p>Thiazide vs. any other: RR=0.94, 95% CI 0.82-1.09</p> <p>β-blockers vs. any other: RR=1.18, 95% CI 1.03-1.36</p> <p>ACE inhibitors vs. any other: RR=1.06, 95% CI 0.94-1.20</p> <p>ARB vs. any other: RR=0.90, 95% CI 0.71-1.13</p> <p>Calcium channel blockers vs. any other: RR=0.91, 95% CI 0.84-0.98</p> <p>The reduction in the risk of stroke was significant, regardless of baseline diastolic BP (6 categories ranging from 70-74 to ≥95 mm Hg) or systolic BP (7 categories ranging from 110-119 to ≥170 mm Hg).</p>
<i>Clinical trials including participants (portion or whole sample) who had sustained a previous stroke or TIA</i>					
<p>Kitagawa et al. 2019</p> <p>Japan</p> <p>RCT</p> <p>The Recurrent Stroke Prevention Clinical Outcome (RESPECT) Study</p>	<p>CA: <input checked="" type="checkbox"/></p> <p>Blinding: Patient: <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/></p> <p>ITT: <input checked="" type="checkbox"/></p>	<p>1,280 patients (2,000 planned) aged 50-85 years with a history of stroke within the previous 30 days to 3 years with a SBP of 130 to 180 mm Hg or DBP of 80 to 110 mm Hg, on a regimen of 0 to 3 antihypertensive medications. Mean age was 67.3 years, 69% were men. 85% of strokes were ischemic, 15% ICH. The median time from qualifying stroke to randomization was 4.6 months</p>	<p>Patients were randomized 1:1 to a standard treatment group with a target of <140/90mm Hg (n = 640) or an intensive treatment group with a target of <120/80 mm Hg (n =640). The study was planned to continue until the number of recurrent strokes in each group reached 244.</p> <p>An updated systematic review was also performed using the results of the present trial in addition to the SPS3 trial, PAST-BP and PODCAST trials (all described below)</p>	<p>Primary outcome: Recurrent stroke</p> <p>Secondary outcomes: Ischemic stroke, ICH, SAH, MI, major vascular event, all-cause mortality, composite of all-cause mortality, nonfatal stroke, and nonfatal MI</p>	<p>The trial was stopped early due to difficulties with recruitment and lack of funding.</p> <p>Mean duration of follow-up was 3.9 years.</p> <p>At 1 year of follow-up, the achieved BP was 132.0/77.5 mm Hg in the standard target group and 123.7/72.8 mm Hg in the intensive target group (mean SBP difference=8.3mm Hg)</p> <p>There were 52 strokes (2.26% per year) in the standard group and 39 (1.65% per year) in the intensive group. The risk of recurrent stroke was not reduced significantly with intensive BP treatment (HR=0.73, 95% CI 0.49-1.11, p=0.15).</p> <p>There were no significant differences between groups for an of the secondary outcomes except a lower recurrence of ICH in the intensive group (0.04% per year vs. 0.46% per year; HR=0.09, 95% CI 0.01-0.70, p=0.02).</p> <p>In the updated meta-analysis, the risk of recurrent stroke was reduced significantly with intensive</p>

<i>pressure component)</i>			Adjustments to medications were made, as appropriate.		<p>per person years, HR=0.81, 95% CI 0.53-1.23, p=0.32).</p> <p>There were (non-significantly) fewer MIs, major vascular events and vascular deaths in the lower target group.</p> <p>In subgroup analysis examining age, sex, history of diabetes, race, region of residence or baseline SBP), no significant interactions were reported.</p> <p>There were no differences between groups in the number of adverse events reported, or adverse events related to blood pressure management.</p>
<p>Beckett et al. 2008</p> <p>UK</p> <p>RCT</p> <p>The Hypertension in the Very Elderly Trial (HYVET) Study</p>	<p>CA: <input checked="" type="checkbox"/></p> <p>Blinding:</p> <p>Patient: <input checked="" type="checkbox"/></p> <p>Assessor <input checked="" type="checkbox"/></p> <p>ITT: <input checked="" type="checkbox"/> (primary analysis)</p>	<p>3,845 patients >80 years of age with persistent hypertension (defined as a sustained systolic blood pressure of 160 mm Hg). 7% of patients had experienced a previous stroke</p>	<p>Patients were randomized to receive 1.5 mg of the diuretic indapamide (sustained release) (n=1,933) or placebo (n=1,912). The ACE inhibitor perindopril (2 or 4 mg), or placebo, was added if necessary, to achieve the target blood pressure of 150/80 mm Hg. Target systolic blood pressure was <150 mm Hg, and target diastolic blood pressure was < 80 mm Hg.</p>	<p>Primary outcome: Fatal or nonfatal stroke at the end of follow-up (2 years)</p> <p>Secondary outcomes: Death from any cause, death from cardiovascular causes, death from cardiac causes, and death from stroke</p>	<p>The median duration of follow up was 1.8 years.</p> <p>12.4% of patients in the active treatment group experienced a fatal or nonfatal stroke at the end of follow-up compared with 17.7% of patients in the placebo group (unadjusted HR=0.70, 95% CI 0.49 to 1.01, p=0.06).</p> <p>Fewer patients in the active treatment group experienced death from stroke (6.5% vs. 10.7%, unadjusted HR= 0.61, 95% CI 0.38 to 0.99, p=0.046) or death from any cause (47.2% vs. 59.6%, unadjusted HR= 0.79, 95% CI 0.65 to 0.95, p=0.02).</p> <p>Fewer patients in the active treatment group experienced any cardiovascular event (33.7% vs. 50.6%, unadjusted HR= 0.66, 95% CI 0.53 to 0.82, <0.001).</p> <p>The number of serious adverse events reported was lower among patients in the active treatment group (358 vs. 448, p = 0.001). Only five of these events (three in the placebo group and two in the active-treatment group) were deemed to be possibly related to the trial medication.</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
Beckett et al. 2012 UK RCT HYVET Study Group (1-year open-label extension)	CA: <input checked="" type="checkbox"/> Blinding: Patient: <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/> ITT: <input checked="" type="checkbox"/> (primary analysis)	To be eligible for entry into the extension portion of the trial, participants only needed to be on double blind treatment at the time of their final visit. 924 patients (92%) in the active treatment group and 788 patients (90%) in the control group continued to receive treatment.	All patients received active treatment for 1 year as per the original study protocol. (indapamide SR 1.5 mg alone (step 1), indapamide SR plus perindopril 2 mg (step 2), and finally indapamide SR plus perindopril 4 mg (step 3).	Same as original protocol	There were no significant between-group differences in the incidence of fatal/nonfatal stroke (9 vs. 4, HR= 1.92, 95% CI 0.59 to 6.22, p=0.28), heart failure (2 vs. 9, HR= 0.28, 95% CI 0.03 to 2.73, p=0.28), or all cardiovascular events (12 vs. 13, HR= 0.78, 95% CI 0.36 to 1.72, p=0.55). The risk of all-cause mortality and cardiovascular mortality was lower in patients previously receiving active treatment (17 vs. 30, HR= 0.48, 95% CI 0.26 to 0.87, p= 0.02 and 2 vs. 9, HR= 0.19, 95% CI 0.04 to 0.87, p=0.03, respectively).
Beckett et al. 2014 UK RCT HYVET Study Group (subgroup and per protocol analyses)	As above	Per original study ITT analysis (n=3845), per protocol analysis (n=3822)	Subgroups included age (80-84.9 years and ≥85 years), sex, history of CVD, baseline SBP (160-169, 170-179, ≥180 mm Hg)	Total mortality, cardiovascular mortality, stroke, heart failure and cardiovascular events	For the outcome of stroke, there was a trend towards reduced risk associated with active treatment across all subgroups. For the outcome of total mortality, the risk was significantly reduced for women, younger patients (80-84.9 yrs) and those without a history of CVD taking active treatment, with trends towards reduced risk for the remaining subgroups. The median follow-up for per protocol patients was 1.7 years. In per protocol analysis, there was a significant reduction in the risk of fatal/non-fatal stroke and stroke mortality associated with active treatment (HR=0.63, 95% CI 0.44-0.92, p<0.016 and HR=0.55, 95% CI 0.33-0.92, p<0.021, respectively).
Yusuf et al. 2008 International RCT (factorial) Ongoing Telmisartan Alone and in Combination	CA: <input checked="" type="checkbox"/> Blinding: Patient <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/> ITT: <input checked="" type="checkbox"/>	25,620 patients with coronary, peripheral, or cerebrovascular disease or diabetes with end-organ damage who could not tolerate ACE inhibitors. Mean age was 66 years, 216% were	Patients were randomized to receive either an ACE-inhibitor (ramipril 10 mg/day, n=8,576), an ARB (telmisartan 80 mg/day, n=8,542) or a combination of both drugs (n=8,502).	Primary outcome: Death from cardiovascular causes, MI, stroke or hospitalization for heart failure Secondary outcomes: Composite outcome of death from cardiovascular causes,	Median follow-up period was 56 months. Death from cardiovascular causes was similar among groups (ramipril: 16.5%, telmisartan 16.7% and combination therapy 16.3%). Death from MI or stroke was similar across groups (ramipril: 4.7%, telmisartan 4.3% and combination therapy 4.4%).

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
with Ramipril Global Endpoint Trial (ONTARGET)		women. 21% had previous stroke or TIA		myocardial infarction, or stroke and new onset of heart failure, diabetes mellitus, atrial fibrillation, dementia or cognitive decline, nephropathy, and revascularization procedures.	<p>Death from any cause was similar across groups (ramipril: 11.8%, telmisartan 11.6% and combination therapy 12.5%).</p> <p>Occurrence of stroke was similar among groups (ramipril: 14.1%, telmisartan 13.9% and combination therapy 14.1%).</p> <p>The use of telmisartan was associated with a higher incidence of hypotensive symptoms ($p<0.001$) than treatment with ramipril. Combination therapy was associated with increased risk of hypotensive symptoms ($p<0.001$), syncope ($p=0.03$) and renal dysfunction ($p<0.001$) when compared to ramipril.</p>
<p>Yusuf et al. 2008, Foulquier et al. 2014</p> <p>International RCT</p> <p>Telmisartan Randomised Assessment Study in ACE intolerant subjects with cardiovascular Disease (TRANSCEND)</p>	<p>CA: <input checked="" type="checkbox"/></p> <p>Blinding: Patient <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/></p> <p>ITT: <input checked="" type="checkbox"/></p>	5,926 high-risk patients who were intolerant to ACE-inhibitors (same design as ONTARGET). Mean age was 67 years, 43% were female, 22% had prior stroke/TIA	Following a 3-week run-in period (week 1- placebo daily, 2 weeks 80 mg telmisartan), patients were randomized to receive either telmisartan (80mg/day, n=2,954) or placebo (n=2,972). All patients received treatment for hypertension with proven therapies, as required	<p>Primary outcome: Composite of cardiovascular death, MI, stroke or hospitalization for heart failure</p> <p>Secondary outcomes: Composite of cardiovascular death, MI or stroke</p> <p>Additional outcomes: new heart failure, development of DM, AF, dementia nephropathy and revascularization.</p>	<p>Main Results Median follow-up was 56 months.</p> <p>Mean blood pressure was significantly lower among patients in the telmisartan group throughout the trial.</p> <p>Non-significantly fewer patients in the telmisartan group experienced the primary outcome (15.7% vs. 17.0%, HR=0.92, 95% CI 0.81-1.05, $p=0.216$). There was no difference between groups in the risk of the individual components of the primary outcome.</p> <p>After adjusting for multiple comparisons, Non-significantly fewer patients in the telmisartan group experienced the composite outcome of cardiovascular death or stroke (13.0% vs. 14.8%, HR=0.87, 95% CI 0.76-1.00, $p=0.068$).</p> <p>No differences between groups were noted based on subgroup analysis (history of CVD, DM, blood pressure, age, sex, HOPE score or statin use)</p> <p>Post hoc analysis (Foulquier et al. 2014)</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
					<p>Analysis of patients who were hypertensive ($\geq 140/90$ mm Hg, $n=5098$) at the start of run in compared with those who were normotensive ($n=828$).</p> <p>Patients who were hypertensive were significantly older, with higher BMIs, higher pulse pressures and rates and a higher percentage had experienced a previous stroke or TIA.</p> <p>There was no significant difference in the risk of any of the outcomes between groups (p for interaction all >0.05).</p> <p>Among patients with hypertension, the risks of the primary and secondary outcomes and MI were significantly lower for patients taking telmisartan, treated after 6 months (vs. ≤ 6 months).</p>

Perindopril Protection Against Recurrent Stroke Study (PROGRESS) Collaborative Group 2001 Australia RCT	CA: <input checked="" type="checkbox"/> Blinding: Patient <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/> ITT: <input checked="" type="checkbox"/>	6,105 patients with a history of stroke (ischemic or hemorrhagic) or TIA within the previous 5 years. No blood pressure entry criteria	Patients who adhered to, and tolerated, the run-in treatment were randomly assigned to continued active therapy (n=3,051) or matching placebo (n=3,054). Patients in the active treatment group received a flexible regimen based on perindopril (4 mg daily) with the addition of indapamide (2.5 mg daily) in patients for whom the responsible physician judged there to be no specific indication for or contraindication to treatment with a diuretic.	Primary outcome: Fatal/nonfatal stroke Secondary outcomes: Fatal or disabling stroke, total vascular events (vascular death, non-fatal MI, non-fatal stroke), death due to any vascular cause Participants were seen 5 times during the first year and then bi-annually up to 4 years.	4-year outcome data was available for all but 3 patients. Mean duration of follow-up was 3.9 years. 22% of patients had discontinued medication by end of study follow-up. Significantly fewer patients in the active treatment group had: a stroke at the end of follow-up (10% vs. 14%, RRR=28%, 95% CI 17%-38 %, p< 0.0001); or suffered a major vascular event (15% vs. 20%, RRR=26%, 95% CI 16% to 34%). There was no significant difference in mortality between groups (10.0% vs. 10.4%, RRR=4%, 95% CI -12% to 18%). Patients treated with combination therapy had fewer strokes compared with patients who received double placebo (8.4% vs. 14.4%, RRR=43%, 95% CI 30% to 54%). The occurrence of stroke in patients treated with single therapy was not significantly different compared with patients who received placebo (12.3% vs. 12.9%). Patients who were both normotensive and hypertensive at baseline had significant reductions in the risk of stroke.
Perry et al. 2000 Additional analysis from Systolic Hypertension in the Elderly	CA: <input checked="" type="checkbox"/> Blinding: Patient <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/> ITT: <input checked="" type="checkbox"/>	4,736 persons aged ≥60 years with systolic blood pressures from 160-219 mm Hg. Mean age was 71.6 years, 43.2% were men. 1.4% had a previous stroke	Subjects were randomized to receive 12.5 mg/d of chlorthalidone. If required to maintain target BP, additional treatment could be added including	Primary outcome: Occurrence, type and subtype of stroke	The average follow-up was 4.5 years. The incidence of all stroke was lower in patients receiving active treatment (103 vs. 159, adjusted risk ratio=0.63, 95% CI 0.49 to 0.81)

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
Program (SHEP) trial USA RCT			25 mg of chlorthalidone, 25 mg/d of atenolol or 0.05 mg/d of reserpine (n = 2,365) or placebo (n = 2,371).		<p>The incidences of ischemic stroke and hemorrhagic were lower in patients receiving active treatment (85 vs.132, adjusted risk ratio=0.63; 95% CI 0.48 to 0.82 and 9 vs. 19 adjusted RR=0.46, 95% CI 0.21 to 1.0, respectively).</p> <p>There was no difference in stroke recurrence between groups (12 vs. 17, p=0.34).</p> <p>Subjects who met pre-specified BP targets were at lower risk for development of stroke.</p>
Hansson et al. 1998 International RCT Hypertension Optimal Treatment (HOT)	CA: <input checked="" type="checkbox"/> Blinding: Patient: <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/> ITT: <input checked="" type="checkbox"/>	18,790 patients, aged 50 to 80 years with diastolic blood pressure between 100 mm Hg and 115 mm Hg. A small number of participants (~1.2%) had experienced a previous stroke	<p>Patients were randomly allocated to 1 of 3 target groups based on diastolic BP; ≤ 90 mm Hg (n=6264), ≤ 85 mm Hg (n=6264) or ≤ 80 mm Hg (n=6262).</p> <p>All patients received a 5-step treatment regimen beginning with felodipine 5 mg/day followed by the addition of ACE inhibitors or β-blockers, increased felodipine, increased ACE-inhibitors or β-blockers and, finally, a diuretic. Additional steps were added, as required to achieve target BP. All patients were then randomized to receive 75 mg of ASA/day (n=9399) or matching placebo (n=9391).</p>	<p>Primary outcome: Major cardiovascular events (fatal and nonfatal MI, strokes and all other cardiovascular deaths)</p> <p>Secondary outcomes: Individual components of primary outcome</p>	<p>There were no differences among groups for the outcomes of major cardiovascular events (232 vs. 234 vs. 217, p=0.5), major cardiovascular events, including silent myocardial infarction (274 vs. 276 vs. 263, p=0.66), all stroke (94 vs.111 vs. 89, p=0.74) or total mortality (188 vs. 194 vs. 207, p=0.32).</p> <p>In 1,501 patients with diabetes mellitus at baseline, the risk of major CV events was doubled for patients in the ≤90 mm Hg group compared with ≤80 mm Hg (RR=2.06, 95% CI 1.24 to 3.44).</p> <p>In 3,080 patients with pre-existing ischemic heart disease, the lowest targeted BP group was associated with the fewest stroke events (p=0.046). There was a 43% reduction of strokes in ≤80 mm Hg target group compared with ≤90 mm Hg target group.</p> <p>Treatment with ASA significantly reduced major cardiovascular events by 15% (p=0.03) and all MI by 36% (p=0.002).</p> <p>There were 7 fatal bleeds in the ASA group and 8 in the placebo group. There were more nonfatal major bleeds in the ASA group (129 vs.70, p<0.001).</p>

					491 (2.6%) patients were lost to follow-up.
<i>Clinical trials including participants at high risk of cardiovascular disease with no history of previous stroke</i>					
White et al. 2019 USA RCT Intensive Versus Standard Ambulatory Blood Pressure Lowering to Prevent Functional Decline In the Elderly (INFINITY)	CA: <input checked="" type="checkbox"/> Blinding: Patient: <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/> ITT: <input checked="" type="checkbox"/>	199 persons ≥75 years, with systolic HTN based on clinic and ambulatory blood pressure measurements, (or SBP 150 to 170 mm Hg if taking ≥1 antihypertensive drugs, or >170 mm Hg if taking 0 to 1 antihypertensive drug at screening) and with visible white matter hyperintensity lesions on MRI (typically ≥0.5% lesion volume). Persons with a history of stroke were excluded. Mean age was 85 years, 54% were women.	Patients were randomized to receive intensive treatment (24-hour SBP target ≤130 mmHg), or to standard treatment (≤145 mmHg),	Primary outcomes: Gait speed, 4-step ascent/decent, sit to stand, supine to sit, unipedal balance, functional reach, accrual of white matter hyperintensity lesions Secondary outcomes: Change in cognitive function (executive function, processing time) Safety outcomes: Mortality, major nonfatal cardiovascular events Outcomes were assessed at 18 and 36 months	The mean 24-hour SBP was 127.7 mmHg in the intensive treatment group and 144.0 mmHg in the standard treatment group (mean difference of 16.3 mmHg). There were no differences between groups in mean changes from baseline and 18 or 36 months in any of the mobility measures. There were no differences between groups in changes from baseline and 36 months in any of the assessments of cognitive function except for the California Computerized Assessment Package Sequential Reaction Time (-23.2 vs. 32.6 msec), favouring the intensive group. The percentage increase in white matter hyperintensity was significantly less in the intensive group (0.29% vs. 0.5%, p=0.03). The risk of a serious cardiovascular event was significantly lower in the intensive group (HR=0.24, 95% CI, 0.08–0.68; P<0.01). The most common event was arrhythmia. There was a single stroke in the intensive group and 2 in the standard group.
Lonn et al. 2016 Canada RCT Heart Outcomes Prevention Evaluation-3 (HOPE-3) (blood-pressure lowering arm)	CA: <input checked="" type="checkbox"/> Blinding: Patient: <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/> ITT: <input checked="" type="checkbox"/>	12,705 men ≥55 and women ≥65 years with at least one cardiovascular risk factor (women ≥60 years with at least 2 risk factors were also eligible), but without known cardiovascular (CV) disease. Persons with an absolute indication for, or contraindication to any of the study medications	2 x 2 factorial design (blood pressure and statin arms). During a 4-week run in period participants took both active study medications. Those who were compliant with treatment and did not suffer adverse events were randomized to receive 16 mg/day candesartan +12.5 mg	Primary outcomes: i) Composite of death from CVD, or nonfatal MI or nonfatal stroke ii) i) + resuscitated cardiac arrest, heart failure or revascularization Secondary outcomes: primary outcome ii) + angina + evidence of ischemia, fatal or nonfatal stroke	Mean baseline blood pressure was similar between groups (combination therapy vs. placebo) SBP: 138.2 vs. 137.9 mm Hg DBP: 82.0 vs. 81.8 mm Hg The median duration of follow-up was 5.6 years. The mean decrease in SBP over the trials was 10.0 mm Hg (combination therapy) and 4.0 mm Hg (placebo). The corresponding mean decreases for DBP were 5.7 and 2.7 mm Hg.

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations

Hao et al. 2014 China Systematic review &	NA	10 RCTs (n=21,871) examining the effects of angiotensin-converting enzyme (ACE) inhibitors and angiotensin II	Treatment contrasts included: ACE inhibitors vs. β -blockers (n=1), ACE inhibitors vs. Ca Channel blockers (n=1),	<p>Primary Outcome: All-cause mortality</p> <p>Secondary outcomes: CV mortality, MI, stroke and</p>	<p>Mean duration of follow-up ranged from 2.5->9 years.</p> <p>Treatment with ACE/ARBs was not associated with a significant reduction in the risk of all-cause</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
meta-analysis		receptor blockers (ARBs) on cardiovascular (CV) risk in hypertensive patients with type 2 diabetes. Mean age of patients ranged from 56-64 years.	ARB vs. placebo (n=1), ACE inhibitor vs. other drugs (n=1), Angiotensin 2 receptor blocker vs. placebo (n=2), ACE inhibitor vs. placebo (n=2), Angiotensin 2 receptor blocker vs. Ca channel blocker(n=2),	CV events	mortality (HR=0.91, 95% CI 0.83-1.00, p=0.062). Treatment with ACE/ARBs, was not associated with a significant reduction in the risk of stroke (HR=0.99, 95% CI 0.85-1.15, p=0.86). Results from 8 trials included.
Arguedas et al. 2013 Costa Rico & Canada Cochrane review	NA	5 RCTs (n=7,314) examining trials comparing 'lower' BP targets (any target <130/85mmHg) with 'standard' BP targets (<140 - 160/90 – 100 mmHg) in people with diabetes. Participants were adults with type II DM and elevated blood pressure, or already receiving treatment for elevated blood pressure. Participants in all included trials were between 40-5 and 70-82 years at baseline.	Treatment contrasts of the included studies: ACCORD-BP: intensive group (SBP <120 mm Hg) vs. standard group (SBP<140 mm Hg) ABCD-H & ABCD-2V: intensive group (DBP <75 mm Hg) vs. moderate group (DBP 80-89 mm Hg) ABCD-N: intensive group (DBP of 10 mm Hg below baseline) vs. standard group (DBP 80-89 mm Hg). HOT subgroup: DBP ≤90 mm Hg vs. ≤85 mm Hg vs. ≤80 mm Hg Hypertensive agents used included Calcium channel blockers, ACE inhibitors and ARBs. In some cases, no specific drug regimen was described.	Primary outcome: All-cause mortality, adverse events Secondary outcomes: Systolic and diastolic BPs achieved, number of antihypertensive agents required.	In the single trial aimed at reductions in SBP (ACCORD) intensive BP control was not associated with reductions in total mortality (RR= 1.05, 95% CI 0.84-1.30) but was associated with reduction in the risk of stroke (RR=0.58, 95% CI 0.39 to 0.88, p= 0.009). In the 4 trials aimed at reductions in DBP, intensive BP control was not associated with reductions in total mortality (RR= 0.73, 95% CI 0.53-1.01, p=0.054) or stroke (RR= 0.67, 95% CI 0.42-1.05, p=0.077).

<p>Heart Outcomes Prevention Evaluation (HOPE) Study Investigators 2000 International RCT</p>	<p>CA: <input checked="" type="checkbox"/></p> <p>Blinding: Patient: <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/></p> <p>ITT: <input checked="" type="checkbox"/></p>	<p>3,577 people with diabetes, ≥ 55 years who had a previous cardiovascular event or at least one other cardiovascular risk factor, no clinical proteinuria, heart failure, or low ejection fraction.</p>	<p>Patients were randomized to receive 10 mg ramipril and 400 IU vitamin E (n=1,808) or placebo (n=1,769), daily for the study duration.</p> <p>The planned follow-up period was 5 years.</p>	<p>Primary outcome: Cardiovascular mortality, stroke and MI at end of follow-up (composite outcome)</p> <p>Secondary outcomes: Total mortality, overt nephropathy</p>	<p>The median duration of follow-up was 4.5 years.</p> <p>The study was stopped 6 months early.</p> <p>Fewer patients in the ramipril group experienced the composite endpoint (15.5% vs. 19.8%, RRR= 25%, 95% CI 12% to 36%, p=0.0004) or fatal or non-fatal stroke (4.2% vs. 6.1%, RRR= 33%, 95% CI 10% to 50%, p=0.0074).</p> <p>Mortality was lower among patients in the ramipril group (10.8% vs. 14.0%, RRR=24%, 95% CI 8% to 37%, p=0.004).</p> <p>Fewer patients in the ramipril group developed overt nephropathy (15.1% vs. 17.6%, RRR=16%, 95% CI 1% to 29%, p=0.036).</p> <p>Cough was one of the most frequently cited reason for stopping study medications. Its frequency was higher among patients in the ramipril group (7% vs. 2%).</p>
<p>Turner et al. 1998 UK RCT United Kingdom Prospective Diabetes Study (UKPDS) 38</p>	<p>CA: <input checked="" type="checkbox"/></p> <p>Blinding: Patient: <input checked="" type="checkbox"/> Assessor <input checked="" type="checkbox"/></p> <p>ITT: <input checked="" type="checkbox"/></p>	<p>1,148 hypertensive patients aged 25-65 years with newly diagnosed type II diabetes and HTN (SBP≥160 mm Hg and DBP≥90 mm Hg, if untreated or ≥150 mm Hg and ≥85 mm Hg, if</p>	<p>Patients were randomly assigned to tight control vs. less tight control of blood pressure groups. Tight control patients received either captopril 25– 50 mg twice daily (n=400) or atenolol 50 – 100 mg/day (n=358)</p>	<p>Primary outcome: Time to occurrence of a first clinical end point related to diabetes (including death, fatal/nonfatal MI, heart failure, stroke), death related to diabetes and all-cause mortality</p>	<p>Median duration of follow-up was 8.4 years.</p> <p>Mean blood pressures (baseline and during study) were: Tight control group: 159/94 vs. 144/82 mm Hg Less tight control group: 160/94 vs. 154/87 mm Hg.</p> <p>There was a reduced risk of developing any end</p>

Study/Type	Quality Rating	Sample Description	Method	Outcomes	Key Findings and Recommendations
<i>(hypertension portion)</i>		treated). Mean age at baseline was 56 years. 55% of patients were male. 36% of patients were receiving treatment for HTN at the start of study.	to achieve a BP of <150/<85 mmHg. Additional agents were added if target blood pressures were not achieved. Less tight control patients (n=390) were treated to achieve a target BP of <180/<105 without the use of an ACE-inhibitor or β -blocker	Secondary outcome: Nonfatal/fatal MI, fatal/nonfatal stroke, amputation or death from peripheral vascular disease and fatal/nonfatal renal failure	point related to diabetes associated with tight blood pressure control (RR=0.78, 95% CI 0.62-0.92, p=0.0042) including any stroke (RR=0.56, 95% CI 0.35-0.89, p=0.013). When analyzed individually, there was no significant risk reduction associated with tight control for the outcomes of fatal stroke (RR=0.42, 95% CI 0.13-1.33) or nonfatal stroke (RR=1.05, 95% CI 0.54-2.06). At the end of study, vital status was known for 96% of participants.

Abbreviations

ARR: absolute risk reduction	CA: concealed allocation	CI: confidence interval
HR: hazard ratio	ITT: intention-to-treat	NNTB: number needed to benefit
NNTH: number needed to harm	OR: odds ratio	RR: relative risk
RRR: relative risk reduction
